

Images and visibilities of objects considered as candidates to geodetic sources

COMPILED BY L. PETROV

March 2, 2007

1.1 Explanation

1.1.1 Introduction

This book contains images of the sources that are considered as candidates to geodetic sources. They have the suitability class 1 or 2. Suitability class 1 (“*perfect*”) means that the source has the compactness, the ratio of the median correlated flux density at baselines longer 5000 km to the median correlated flux density at baselines shorter than 900 km, greater than 0.8, and it has a very small spread at plots of calibrated visibilities versus the length of the baseline projected to the plane normal to the source direction, because it does not have asymmetries in the image. The suitability class 2 means that the sources has compactness index in the range 0.4–0.8, does not have a significant spread at plots of calibrated visibilities versus the length of the projected baseline, the image does not show significant extended details, and the core does not have significant deviations from the circular structure.

1.1.2 Data Presentation

The image information is split into frames, four frames per page. Each frame consists of five figures and auxiliary information. For some sources images for more than one epoch are available.

The uv -coverage of the experiment used for producing the image is shown in a small figure at the upper left corner of the frame. The IAU J2000 name of the source is shown using **black** color at the upper line near the figure with the uv coverage. The IVS source name is shown at the upper right corner using either **red** or **purple** color. **Red** color is used if the source is listed before 2007 as geodetic, otherwise **purple** color is used.

The table with correlated the integrated flux density, the flux density at short and long baselines for both **S band** and **X bands** is shown beneath the IAU J2000 source name . The integrated flux density in the first column of the table is defined as the sum of flux densities of all δ -function components of the image. The correlated flux density at short baselines in the second column is defined as the median value of the correlated flux density averaged over intermediate frequencies of the band and over time within a scan at baselines with projections to the source plane shorter than 900 km. The correlated flux density at long baselines in the third column is defined as the median value of the correlated flux density averaged over intermediate frequencies of the band and over time within a scan at baselines with projections to the source plane longer than 5000 km.

At the right hand side of the top of each frame a concise statistics is shown: the total number of astrometry/geodesy experiments in which the source was observed and the number of good X/S observations used in astrometric solutions. The epoch of the experiment used for imaging and the name of the person who produced the image are shown at the next line.

The total number of frames for and the index of the frame for this source are shown in the line beneath the IVS source name, for example, **Exp. x (y)**, where y is the total number of frames, and x is the frame index.

S band and **X-band** images are shown in the left bottom corner of the frame. The default image box is $[-50, +50]$ mas for an **S band image** and $[-15, +15]$ mas for an **X band image**. However, if the image has details with correlated flux density greater than 3 times the rms of the image noise, the image box is extended to show this detail. The top of the image caption shows the observation epoch, the IAU J2000 source name and the central sky frequency. The bottom of the image caption shows the peak correlated flux density and the correlated flux densities of each contour levels. The first contour level is set to 3 times the rms of the image noise. The contour levels forms the geometric progression with the base 2. The following algorithm was used for computing the rms of the image noise. The rms of the flux density in four corners, each of 1/4 size of the original image, i.e. 1/16 of the image area, is computed independently. The maximal over 4 estimates of the rms noise is discarded, and the remaining three estimates are averaged. At the second iteration the rms

in three remaining corners is computed the second times using the iterative procedure. The points which exceed the 4 times the rms estimated at the first iteration are discarded. The response of the interferometer to a point-like source, the so called “clean beam”, is shown in the bottom left corner. The response is modeled by a two-dimensional Gaussian function. The area at 0.5 of the peak value of the response is shown by gray color.

The details of the analysis technique varied. In general, the first step of the analysis, fringe search, a priori calibration, flagging, data splitting, was performed by AIPS. The second step, image restoration, calibration adjusting, tapering, was performed by DIFMAP, first running it in a batch mode, then after visual inspection, running DIFMAP for a part (or all) sources manually.

The dependence of the correlated flux density on the length of the baseline projection to the image plane at **S band** and **X-bands** are shown in plots of the bottom right frame corner. Each point represents the amplitude of the complex visibility averaged over frequency of the band and over time within a scan. Observations with time tags greater than 300 seconds are considered to belong to different scans. The rms of the averaged visibility for each point was computed on the basis of their scatter with respect to the mean value. The vertical error bar at the plot corresponds to the 1σ error. The points with errors greater than $f * \text{Amp}$, where **Amp** is the averaged visibility and f is a certain factor, are not shown. The factor f was selected depending on experiment in the range of [0.25, 0.50].

1.1.3 Credit

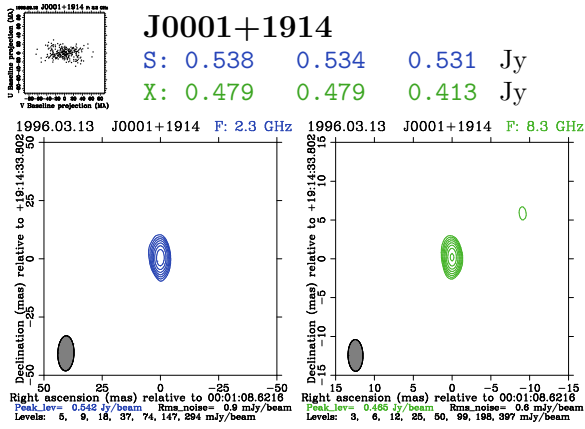

The images were produced by analyzing observation at the very long baseline interferometer of the the National Radio Astronomy Observatory. The National Radio Astronomy Observatory is a facility of the National Science Foundation operated under cooperative agreement by Associated Universities, Inc. Many individuals contributed to scheduling, observations and data analysis. The final images were generated by
